

SOFT1902 project

From Nointrigue

Software Development in Semester 2, 2004 brought something of a different flavour from Semester 1. We were asked to design a multithreaded client-server database system. The result? **Project Management System 2004** (PMS) is a fully-functioning database system designed to allow businesses to manage their resources.

Description

When managing projects, whether software development or otherwise, organisations must find a way to organise their resources — files, people, events. PMS 2004 makes that easy. It keeps track of projects and their related users, events and files, and allows centralised access to any of those components anywhere in the world while maintaining strict security through a group-based permissions system, and data encryption. As it even comes with its own Java-like scripting language, maintenance can be easily performed with a single command.
